## Objects of the experiment

- Determination of the distance as function of inclination angle.
- Determination of the maximum height as function of the inclination angle.

## Principles

In the experiment a steel ball of mass $m$ is projected at an angle $\alpha$ to the horizontal with an initial velocity $\mathrm{v}_{0}$. The motion of the steel ball in the (constant) gravitational field lies in a plane and can be described by the equation (Fig. 1):
$\mathrm{m} \frac{\mathrm{d}^{2} \vec{r}}{\mathrm{dt}^{2}}=\mathrm{m} \cdot\binom{0}{-\mathrm{g}}$
$\vec{r}=\binom{x}{y}$ : vector of location
m : mass of the steel ball
$\vec{F}=m \cdot\binom{0}{-g}$ : force acting on the steel ball

Fig. 1: Movement of a mass in a constant gravitational field. Sche-
Fig. 1: Movement of a mass in a constant gravitational field. Schedescription of the motion with equation (I).

Solving equation (I) for the initial conditions
$\vec{r}(0)=\binom{0}{0} \quad$ and $\quad \vec{v}(0)=\binom{v_{0} \cdot \cos \alpha}{v_{0} \cdot \sin \alpha}$
lead to the coordinates of the steel ball as function of time $t$ :
$x(\mathrm{t})=\mathrm{v}_{0} \cdot \cos \alpha \cdot \mathrm{t}$
$y(t)=v_{0} \cdot \sin \alpha \cdot t-\frac{1}{2} g \cdot t^{2}$
Form this the range s and the maximum height h is obtained as function of the inclination angle $\alpha$ and the initial velocity $\mathrm{v}_{0}$ :
$\mathrm{s}=\frac{\mathrm{v}_{0}^{2}}{\mathrm{~g}} \sin 2 \alpha$
$\mathrm{h}=\frac{\mathrm{v}_{0}^{2}}{2 \mathrm{~g}} \sin ^{2} \alpha$
In this experiment the range s and the maximum height h as function of the inclination angle $\alpha$ are determined for three different initial velocities $v_{0}$.
Apparatus
1 Large projection apparatus ..... 33656
2 Bench clamp ..... 30106
1 Vertical scale, 1 m ..... 31122
1 Steel tape measure, 2 m ..... 31177
1 Saddle base ..... 30011
1 Laboratory stand II ..... 30076
1 Tray, $552 \times 197 \times 48 \mathrm{~mm}$ ..... 64942
1 Bottle of quartz sand, 1 kg ..... 30900743

## Safety notes

Please observe the recommendation of the label on the projection apparatus containing the safety notes.
Do not allow a finger to enter the danger region while setting or releasing the projection apparatus.
Be careful not to crush any part of your hand.

## Setup

- Mount the projection apparatus as depicted in Fig. 2 on a table.
- Place the tray on the laboratory stand.
- Adjust the height of the surface that either the surface of the sand (method I) or the carbon paper on a white sheet of paper (method II) in the tray is at the same height $(10 \mathrm{~cm})$ with the steel ball in the projection apparatus.
- To measure the maximum height h of the trajectory clamp the scale in the saddle base.

## Carrying out the experiment

a) Determination of the range as function of inclination angle

- Measure the range $s$ as function of the inclination angle $\alpha$ for a fixed initial velocity $\mathrm{v}_{0}$.
- Repeat the measurement for the other two possible stages of compression of the projection apparatus, i.e. other two possible initial velocities $\mathrm{v}_{0}$.
Note: The points of impact can be recorded either by using sand in the tray (method I) or by using carbon paper on top of a white sheet of paper (method II). For method II it is recommended to secure the white sheet of paper with adhesive tape and number the points of arrival in the sequence of throws (see also instruction sheet 336 56).

Fig. 2: Schematic diagram of the experimental setup to determine the range and the height as function of the projection angle. Compare instruction sheet 33656 for further modifications
b) Determination of the height as function of inclination angle

- Measure the maximum height h as function of the inclination angle $\alpha$ for a fixed initial velocity $\mathrm{v}_{0}$.
- Repeat the measurement for the other two velocities $\mathrm{v}_{0}$, i.e. the other two positions of the projection apparatus.

Note: The maximum height $h$ of the of the trajectory can be determined quite well using the movable pointers of the vertical scale. For further information see also instruction sheet 33656.

## Measuring example

a) Determination of the range as function of inclination angle
Table 1: Range $s$ as function of the inclination angle $\alpha$ for three different initial velocities of the projection apparatus.

| $\frac{\alpha}{\operatorname{deg}}$ | $\frac{\mathrm{s}_{1}}{\mathrm{~m}}$ | $\frac{\mathrm{~s}_{2}}{\mathrm{~m}}$ | $\frac{\mathrm{~s}_{3}}{\mathrm{~m}}$ |
| :---: | :---: | :---: | :---: |
| 10 | 0.130 | 0.330 | 0.630 |
| 15 | 0.210 | 0.430 | 0.900 |
| 20 | 0.265 | 0.580 | 1.180 |
| 25 | 0.320 | 0.715 | 1.390 |
| 30 | 0.365 | 0.825 | 1.545 |
| 35 | 0.390 | 0.900 | 1.670 |
| 40 | 0.410 | 0.930 | 1.705 |

## Evaluation and results

Fig. 3: Range $s$ as function of the inclination angel $\alpha$ for three different initial velocities $\mathrm{v}_{0}$. Solid lines correspond to a least square fit according equation (III).

Form Fig. 3. the initial velocities $\mathrm{v}_{0}$ can be determined for $\alpha=45^{\circ}$ using equation (III):

$$
\begin{aligned}
& \mathrm{v}_{1}=2.0 \frac{\mathrm{~m}}{\mathrm{~s}} \\
& \mathrm{v}_{2}=3.0 \frac{\mathrm{~m}}{\mathrm{~s}} \\
& \mathrm{v}_{3}=4.1 \frac{\mathrm{~m}}{\mathrm{~s}}
\end{aligned}
$$

Fig. 4: Maximum height h as function of the inclination angel $\alpha$ for three different initial velocities $\mathrm{v}_{0}$. Solid lines correspond to a least square fit according equation (IV).

Observable deviations from the parabolic form may be due to friction with the air.
Fig. 3 and Fig. 4 confirm equation (III) and (IV) which have been derived under the assumption of a superposition of a motion with constant velocity in the direction of projection and a vertical falling motion. The trajectory of the steel ball is a parabola whose width and height depend on the inclination angle and the initial velocity.

## Supplementary information

The initial velocity $\mathrm{v}_{0}$ can be measured by using a forked light barrier ( 337 46). For details of the experimental setup see instruction sheet 33656 . The values measured directly can be compared with the initial velocities found by a least square fit to the experimental data of part a) depicted e.g. in Fig. 3:

Table 3: Comparison of measured initial velocities $v_{0}$ with the result of experiment a).

|  | experiment a) | measured <br> (light barrier) |
| :---: | :---: | :---: |
| $\frac{\mathrm{v}_{1}}{\mathrm{~m} / \mathrm{s}}$ | 2.0 | 2.1 |
| $\frac{\mathrm{v}_{2}}{\mathrm{~m} / \mathrm{s}}$ | 3.0 | 3.1 |
| $\frac{\mathrm{v}_{3}}{\mathrm{~m} / \mathrm{s}}$ | 4.1 | 4.0 |

The measurement of $\mathrm{v}_{0}$ using the light barrier also allows to show that the initial velocity $v_{0}$ is independent of inclination angle $\alpha$.
